Keywords: Polymorphism, continuations

Abstract. Meyer and Wand established that the type of a term in the simply typed \( \lambda \)-calculus may be related in a straightforward manner to the type of its call-by-value CPS transform. This typing property may be extended to Scheme-like continuation-passing CPS transforms, from which the soundness of these extensions follows. We study the extension of these results to the Damas-Milner polymorphic type assignment system under both the call-by-value and call-by-name interpretations. We obtain CPS transforms for the call-by-value interpretation, provided that the polymorphic \( \text{let} \) is restricted to values, and for the call-by-name interpretation with no restrictions. We prove that there is no call-by-value CPS transform for the full Damas-Milner language that validates the Meyer-Wand typing property and is equivalent to the standard call-by-value transform up to operational equivalence.

1. Introduction

In their study of the relationship between direct and continuation semantics for the simply typed \( \lambda \)-calculus (\( \lambda^- \)), Meyer and Wand note that the type of a term in \( \lambda^- \) may be related in a simple and natural way to the type of its call-by-value continuation passing style (CPS) transform [13]. This result may be extended to the calculus that results from extending \( \lambda^- \) with Scheme-like continuation-passing primitives \( \text{callcc} \) and \( \text{throw} \) (\( \lambda^- + \text{cont} \)) [1, 4]. Since \( \lambda^- \) under a call-by-value operational semantics is “type safe” in the sense of Milner [14, 2], and since the call-by-value CPS transform faithfully mimics the call-by-value semantics [17], it follows that

\( \lambda \rightarrow + \text{cont} \) under a call-by-value operational semantics is also type safe.

In a subsequent study Duba, Harper, and MacQueen studied the addition of \texttt{callcc} and \texttt{throw} to Standard ML [15]. The extension of the Meyer-Wand transform to \( \lambda \rightarrow + \text{cont} \) establishes the soundness of the monomorphic fragment of the language, but the soundness of the polymorphic language with continuation-passing primitives was left open. It was subsequently proved by the authors [9] that the full polymorphic language is unsound when extended with \texttt{callcc} and \texttt{throw}. The source of this discrepancy may be traced to the interaction between the polymorphic \texttt{let} construct and the typing rules for \texttt{callcc}. Several \textit{ad-hoc} methods for restricting the language to recover soundness have been proposed [8, 23].

In this paper we undertake a systematic study of the interaction between continuations and polymorphism by considering the typing properties of the CPS transform for both the call-by-value and call-by-name variants of the Damas-Milner language [2] and its extension with continuation-passing primitives. We obtain suitable extensions of the Meyer-Wand theorem for the call-by-value CPS transform, provided that the polymorphic \texttt{let} is restricted to values, and for the call-by-name transform, under no restrictions. Finally, we prove that there is no call-by-value CPS transform for the full Damas-Milner language that both satisfies the Meyer-Wand typing property and is equivalent to the usual transform up to operational equivalence. In particular, the standard call-by-value CPS transform fails to preserve typability.

## 2. Untyped Terms

The language of untyped terms is given by the following grammar:

\[
e ::= x \mid \lambda x.e \mid e_1 e_2 \mid \text{let } x \text{ be } e_1 \text{ in } e_2 \mid \text{callcc} \mid \text{throw}
\]

Here \( x \) ranges over a countably infinite set of variables. We include the \texttt{let} construct as a primitive because it is needed in the discussion of polymorphic type assignment. The constants \texttt{callcc} and \texttt{throw} stand for continuation-passing primitives whose definitions are derived from analogous constructs in Scheme [1] and Standard ML of New Jersey [4].

We consider two CPS transforms for untyped terms, corresponding to the call-by-value and call-by-name operational semantics [17]. Each CPS transform consists of a transformation \( \triangleright \) for untyped terms and a transformation \( ||\triangleright|| \) for untyped values. Exactly what is considered a value depends on which operational semantics is being used. Under a call-by-value interpretation, the set of values is given by the following grammar:

\[
v ::= x \mid \lambda x.e \mid \text{callcc} \mid \text{throw}
\]
Since \textit{throw} is a two-argument function, it is possible to regard \textit{throw} as a value. We choose to not regard it as a value because to do so complicates somewhat both the transform and the associated theorems due to the resulting overlap between the application and value cases. Under a call-by-name interpretation, the set of values is given by the following grammar:

\[
\begin{align*}
n & ::= \lambda x.e \mid \text{callcc} \mid \text{throw} \\
|v|_{cbv} & = \lambda k.k |v|_{cbv} \\
|e_1 e_2|_{cbv} & = \lambda k.e_1|_{cbv} (\lambda x_1.e_2|_{cbv} (\lambda x_2.x_1 x_2 k)) \\
|\text{let } x \text{ be } e_1 \text{ in } e_2|_{cbv} & = \lambda k.e_1|_{cbv} (\lambda x.e_2|_{cbv} k) \\
|\text{callcc}|_{cbv} & = \lambda f.\lambda k.f k k \\
|\text{throw}|_{cbv} & = \lambda c.\lambda k.k (\lambda x.\lambda l.c x)
\end{align*}
\]

The transformation of \textit{let} expressions is chosen to reflect the usual “sequential” evaluation strategy for \textit{let}'s in a call-by-value language in which the \textit{let}-bound expression, \(e_1\), is fully evaluated prior to evaluation of the body, \(e_2\). (Compare this with the call-by-name transform in Definition 2 below.) The transformation of \textit{callcc} differs from that in Scheme since continuations are not here represented as functions which are applied to their arguments, but rather are represented directly as continuations which are invoked using the \textit{throw} primitive. (See Harper, Duba, and MacQueen [8] for further discussion of this point.)

The call-by-value CPS transform is compositional in the sense that it commutes with substitution.

**Lemma 1**

1. \(|v/x|e|_{cbv} = \left(\left|v\right|_{cbv}/x\right)\mid|e|_{cbv}\).
2. \(|v/x|e|_{cbv} = \left(\left|v\right|_{cbv}/x\right)\mid|e|_{cbv}\).

**Proof:** The proof proceeds by simultaneous induction on the structure of \(v'\) and \(e\). We give here a few illustrative cases; the remainder follow by a similar argument. We drop the “\(cbv\)” subscript for the sake of readability.

\(^1\)In each equation any bound variable occurring on the right that does not also occur on the left is assumed to be chosen so as to avoid capture.
\[ v' = x : \]
We have by definition \[ ||v'|| = x, \] and hence \[ ||v'/x|| = ||v'|| = ||v'/x||. \]

\[ v' = x' \neq x : \]
We have by definition \[ ||x'|| = x', \] and hence \[ ||v'/x|| = x' = ||v'/x||. \]

\[ v' = \lambda y.e : \]
We may assume without loss of generality that \( y \neq x \) and that \( y \) does not occur freely in \( ||v'||. \)

\[ ||[v/x] \lambda y.e|| = ||[\lambda y.[v/x] e]|| \]
\[ = [\lambda y.[v/x] e] \]  (by induction)
\[ = [[v/x]] [\lambda y.e] \]
\[ = [[v/x]] ||[\lambda y.e]|| \]

\[ e = v' : \]
We may assume without loss of generality that \( k \) does not occur freely in \( ||v'||. \) Note that values are stable under substitution of a value for a variable.

\[ [[v/x] v'] = \lambda k.k ||[v/x] v'|| \]  (\( [v/x] v' \) is a value)
\[ = \lambda k.k ||[v/x] v'|| \]  (by induction)
\[ = [[v/x]] [\lambda k.k] ||v'|| \]
\[ = [[v/x]] ||v'|| \]

\[ e = e_1 e_2 : \]
We may assume without loss of generality that the variables \( x_1, \) \( x_2, \) and \( k \) do not occur freely in \( ||v'||. \)

\[ [[v/x] (e_1 e_2)] = [[v/x] e_1 [v/x] e_2] \]
\[ = \lambda k.1 [v/x] e_1 (\lambda x_1.1 [v/x] e_2) \]  \((\lambda x_2.x_1 x_2 k))
\[ = \lambda k.1 [v/x] e_1 (\lambda x_1.1 [v/x] e_2) \]  \((\lambda x_2.x_1 x_2 k))
\[ = [[v/x] [\lambda k.1 e_1] (\lambda x_1.1 e_2) \]  \((\lambda x_2.x_1 x_2 k))
\[ = [[v/x] [\lambda k.1 e_1] \]

We shall also have need of a variant call-by-value CPS transform \((cbv')\) defined on untyped terms satisfying the restriction that all let expressions are of the form \( \text{let } x \text{ be } v \text{ in } e \) — i.e., the let-bound expression is required to be a (call-by-value) value. Because of this restriction, a simpler rule can be given for the let case:

\[ ||\text{let } x \text{ be } v \text{ in } e||_{cbv'} = \lambda k. \text{let } x \text{ be } ||v||_{cbv'} \text{ in } (||e||_{cbv'} k) \]

This simpler rule for let expressions is the only difference between the two transforms.
Lemma 2  Let \( v \) and \( v' \) be values obeying the restriction on let expressions and \( e \) be a term obeying the restriction on let expressions. Then

1. \( \left\| \left[ \left[ v/x \right]\right] v' \right\|_{cbv'} = \left[ \left\| \left[ v\right]/x \right\|_{cbv'} \right]\left\| v' \right\|_{cbv'} \).
2. \( \left\| \left[ v/x \right] e \right\|_{cbv'} = \left[ \left\| \left[ v\right]/x \right\|_{cbv'} \right]\left\| e \right\|_{cbv'} \).

Definition 2 (Call-by-Name CPS Transform) \(^2\)

\[
\begin{align*}
|n|_{cbn} &= \lambda k. \left\| n \right\|_{cbn} \\
|x|_{cbn} &= x \\
|e_1 e_2|_{cbn} &= \lambda k. \left\| e_1 \right\|_{cbn} (\lambda x_1.x_1 |e_2|_{cbn} k) \\
|\text{let } x \text{ be } e_1 \text{ in } e_2|_{cbn} &= \lambda k. \text{let } x \text{ be } |e_1|_{cbn} \text{ in } (|e_2|_{cbn} k) \\
|\lambda x.e|_{cbn} &= \lambda k. |e|_{cbn} \\
|\text{callcc}|_{cbn} &= \lambda f. \lambda k. f (\lambda f'. f' (\lambda l.l k) k) \\
|\text{throw}|_{cbn} &= \lambda c. \lambda k. (\lambda x.c (\lambda x'. e (\lambda x'. e' x'))) \\
\end{align*}
\]

The reader may find it helpful to bear in mind that in call-by-name variables are bound to suspensions, rather than to values. The rather complicated definitions of \( |\text{callcc}|_{cbn} \) and \( |\text{throw}|_{cbn} \) may be attributed to this fact.

Lemma 3

1. \( \left\| \left[ e/x \right] n \right\|_{cbn} = \left[ \left\| e\right|_{cbn}/x \right]\left\| n \right\|_{cbn} \).
2. \( \left\| \left[ e/x \right] e' \right\|_{cbn} = \left[ \left\| e\right|_{cbn}/x \right]\left\| e' \right\|_{cbn} \).

Proof: By simultaneous induction on the structure of \( n \) and \( e' \). 

The relationship between the call-by-value and call-by-name CPS transforms and the corresponding call-by-value and call-by-name operational semantics was established for pure \( \lambda \)-terms by Plotkin [17] and was extended to continuation-passing primitives (for the call-by-value case) by Griffin [6]. (See also [5, 19, 20, 21, 3].)

Theorem 1 (Plotkin, Griffin) The closed expression \( e \) evaluates to \( v \) under call-by-value iff \( |e|_{cbv} (\lambda x.x) \) evaluates to \( |v|_{cbv} \) under either call-by-value or call-by-name.

In particular, if \( e \) evaluates to a constant \( c \), then \( |e|_{cbv} (\lambda x.x) \) evaluates to \( c \), and vice-versa, assuming that \( |e|_{cbv} = c \). A similar result for the call-by-name interpretation may also be proved [17].

\(^2\)In each equation any bound variable occurring on the right that does not also occur on the left is assumed to be chosen so as to avoid capture.
3. Simple Type Assignment

In this section we review Meyer and Wand’s typing theorem for the call-by-value CPS transform for the simply-typed $\lambda$-calculus ($\lambda^\rightarrow$), and present an analogous result for the call-by-name CPS transform.

**Definition 3 ($\lambda^\rightarrow$ Types and Contexts)**

\[
\begin{align*}
\text{types}& \quad \tau ::= b \mid \tau_1 \rightarrow \tau_2 \\
\text{contexts}& \quad \Gamma ::= \bullet \mid \Gamma, x:\tau
\end{align*}
\]

Here $b$ ranges over a countable set of base types. We assume that among the base types there is a distinguished type $\alpha$, which will be used in what follows to represent the “answer” type of a CPS transform.

**Definition 4 ($\lambda^\rightarrow$ Typing Rules)**

\[
\begin{align*}
\Gamma \vdash x : \Gamma(x) & \quad \text{(VAR)} \\
\frac{\Gamma, x:\tau_1 \vdash e : \tau_2 \quad (x \not\in \text{dom}(\Gamma))}{\Gamma \vdash \lambda x.e : \tau_1 \rightarrow \tau_2} & \quad \text{(ABS)} \\
\frac{\Gamma \vdash e_1 : \tau_2 \rightarrow \tau \quad \Gamma \vdash e_2 : \tau_2}{\Gamma \vdash e_1 \ e_2 : \tau} & \quad \text{(APP)} \\
\frac{\Gamma \vdash e_1 : \tau_1 \quad \Gamma, x:\tau_1 \vdash e_2 : \tau \quad (x \not\in \text{dom}(\Gamma))}{\Gamma \vdash \text{let } x \text{ be } e_1 \text{ in } e_2 : \tau} & \quad \text{(MONO-LET)}
\end{align*}
\]

The type system $\lambda^\rightarrow + \text{cont}$ is defined by adding the type expression $\tau \text{ cont}$ and the following typing rules for the continuation-passing primitives:

\[
\begin{align*}
\Gamma \vdash \text{callcc} : (\tau \text{ cont} \rightarrow \tau) \rightarrow \tau & \quad \text{(CALLCC)} \\
\Gamma \vdash \text{throw} : \tau \text{ cont} \rightarrow \tau \rightarrow \tau' & \quad \text{(THROW)}
\end{align*}
\]

**Definition 5 (Call-by-Value Type Transform for $\lambda^\rightarrow$)**

\[
\begin{align*}
|\tau|_{cbv} & = (|\tau|_{cbv} \rightarrow \alpha) \rightarrow \alpha \\
|b|_{cbv} & = b \\
|\tau_1 \rightarrow \tau_2|_{cbv} & = |\tau_1|_{cbv} \rightarrow |\tau_2|_{cbv}
\end{align*}
\]
The type transform is extended to contexts by defining $\|\Gamma\|_{cbv}(x) = \|\Gamma(x)\|_{cbv}$ for each $x \in \text{dom}(\Gamma)$.

**Theorem 2 (Meyer-Wand)**

1. If $\lambda \vdash \Gamma \triangleright v : \tau$, then $\lambda \vdash \|\Gamma\|_{cbv} \triangleright \|v\|_{cbv} : \|\tau\|_{cbv}$.
2. If $\lambda \vdash \Gamma \triangleright e : \tau$, then $\lambda \vdash \|\Gamma\|_{cbv} \triangleright \|e\|_{cbv} : \|\tau\|_{cbv}$.

The call-by-value type transform is extended to $\lambda^- + \text{cont}$ by defining $\|\tau \text{ cont}\|_{cbv} = \|\tau\|_{cbv} \rightarrow \alpha$. It is straightforward to verify that Theorem 2 extends to $\lambda^- + \text{cont}$ in this way [4].

**Definition 6 (Call-by-Name Type Transform for $\lambda^-$)**

$\|\tau\|_{cbn} = (\|\tau\|_{cbn} \rightarrow \alpha) \rightarrow \alpha$

$\|b\|_{cbn} = b$

$\|\tau_1 \rightarrow \tau_2\|_{cbn} = \|\tau_1\|_{cbn} \rightarrow \|\tau_2\|_{cbn}$

The type transform is extended to contexts by defining $\|\Gamma\|_{cbn}(x) = \|\Gamma(x)\|_{cbn}$ for each $x \in \text{dom}(\Gamma)$.

**Theorem 3**

1. If $\lambda \vdash \Gamma \triangleright n : \tau$, then $\lambda \vdash \|\Gamma\|_{cbn} \triangleright \|n\|_{cbn} : \|\tau\|_{cbn}$.
2. If $\lambda \vdash \Gamma \triangleright e : \tau$, then $\lambda \vdash \|\Gamma\|_{cbn} \triangleright \|e\|_{cbn} : \|\tau\|_{cbn}$.

The call-by-name CPS transform is extended to $\lambda^- + \text{cont}$ by defining $\|\tau \text{ cont}\|_{cbn} = \|\tau\|_{cbn} \rightarrow \alpha$, just as for call-by-value. It is straightforward to verify that Theorem 3 extends to $\lambda^- + \text{cont}$ in this way.

**4. Polymorphic Type Assignment**

In this section we study the extension of the Meyer-Wand typing property to Damas and Milner’s polymorphic type assignment system (DM).

The syntax of types and contexts in (DM) is defined by the following grammar:

---

3The term “call-by-name type transform” is something of a misnomer since there exists a by-value CPS transform that validates the by-name typing property [20, 7]. Nevertheless we stick with the suggestive, if somewhat misleading, terminology.
Here $t$ ranges over a countably infinite set of type variables. The typing rules of the Damas-Milner system extend those of $\lambda^\to$ as follows:

**Definition 8 (Additional DM Typing Rules)**

\[
\frac{\Gamma \vdash e : \sigma}{\Gamma \vdash e : \forall t.\sigma} \quad (t \notin FTV(\Gamma))
\]

\[
\frac{\Gamma \vdash e : \forall t.\sigma}{\Gamma \vdash e : [\tau/t]\sigma}
\]

\[
\frac{\Gamma \vdash e_1 : \sigma_1 \quad \Gamma, x:\sigma_1 \vdash e_2 : \tau_2}{\Gamma \vdash \text{let } x \text{ be } e_1 \text{ in } e_2 : \tau_2} \quad (x \notin \text{dom}(\Gamma))
\]

The system $\text{DM} + \text{cont}$ is defined by adding the type expression $\tau \text{ cont}$, as before, and adding the following typing rules:

\[
\frac{}{\Gamma \vdash \text{callcc} : \sigma_{\text{callcc}}} \quad \text{(CALLCC')}
\]

\[
\frac{}{\Gamma \vdash \text{throw} : \sigma_{\text{throw}}} \quad \text{(THROW')}
\]

where $\sigma_{\text{callcc}} = \forall t.(t \text{ cont} \to t) \to t$ and $\sigma_{\text{throw}} = \forall s.\forall t.s \text{ cont} \to s \to t$.

### 4.1. Restricted Call-by-Value

Let $\text{DM}^-$ denote the sub-system of $\text{DM}$ obtained by restricting let expressions so that the bound expression is a call-by-value value. The Meyer-Wand typing theorem may be extended to terms of $\text{DM}^-$, provided that we use the variant call-by-value CPS transform ($cbv'$) given in Section 2.

**Definition 9 (Call-by-Value Type Transform for $\text{DM}^-$)**

\[
\begin{align*}
|\tau|_{cbv} &= (|\tau|_{cbv} \to \alpha) \to \alpha \\
|\forall t.\sigma|_{cbv} &= \forall t.|\sigma|_{cbv} \\
|t|_{cbv} &= t \\
|b|_{cbv} &= b \\
|\tau_1 \to \tau_2|_{cbv} &= |\tau_1|_{cbv} \to |\tau_2|_{cbv} \\
|\forall t.\sigma|_{cbv} &= \forall t.|\sigma|_{cbv}
\end{align*}
\]
This definition extends the Meyer-Wand type transform to polymorphic types. In the terminology of Reynolds [19], polymorphic instantiation is given a “trivial” interpretation in that no interesting computation can occur as a result of polymorphic instantiation. The definition of $|∀t.σ|_{cbv}$ reflects the fact that in $DM^-$ there is no need of continuations whose domain is a polymorphic type.

**Lemma 4**

1. $|\{\tau/t\}|_{cbv} = [|\{\tau\}|_{cbv} / t] |\{σ\}|_{cbv}.
2. $|\{τ/t\}|_{cbv} = [|\{τ\}|_{cbv} / t] |\{σ\}|_{cbv}.$

**Proof:** By induction on the structure of $σ$. □

With this in mind we may establish type preservation for the variant call-by-value CPS transform on the sublanguage $DM^-.

**Theorem 4**

1. If $DM^- ⊢ σ : τ$ and $DM^- ⊢ |\{Γ\}|_{cbv} ⊢ |\{v\}|_{cbv'} : |\{σ\}|_{cbv}$, then $DM^- ⊢ |\{Γ\}|_{cbv} ⊢ |\{v\}|_{cbv'} : |\{σ\}|_{cbv}$.
2. If $DM^- ⊢ σ : τ$ and $DM^- ⊢ |\{Γ\}|_{cbv} ⊢ |\{e\}|_{cbv'} : |\{σ\}|_{cbv'}$, then $DM^- ⊢ |\{Γ\}|_{cbv} ⊢ |\{e\}|_{cbv'} : |\{σ\}|_{cbv'}$.

**Proof:** Both parts are proved simultaneously by induction on the structure of typing derivations. We give a few illustrative cases; the rest follow a similar pattern.

**VAR** Suppose that $DM^- ⊢ Γ ⊢ x : σ$ by an application of rule VAR. Then $Γ(x) = σ$, and thus $DM^- ⊢ |\{Γ\}|_{cbv} ⊢ |\{x\}|_{cbv'} : |\{σ\}|_{cbv}$ since $|\{x\}|_{cbv'} = x$.

**ABS** Suppose that $DM^- ⊢ Γ ⊢ λx.e : σ_1 → σ_2$ by an application of rule ABS. Then $DM^- ⊢ Γ, x:σ_1 ⊢ e : σ_2$, where $x \notin \text{dom}(Γ)$, by a smaller typing derivation. Therefore we have, by induction, $DM^- ⊢ |\{Γ\}|_{cbv} ▷ |\{e\}|_{cbv'} : |\{σ_2\}|_{cbv}$, and consequently that $|\{Γ\}|_{cbv} ▷ |\{λx.e\}|_{cbv'} : |\{σ_1\}|_{cbv} → |\{σ_2\}|_{cbv}$. The result follows from the definitions of the term and type transforms.

**LET** Suppose that $DM^- ⊢ Γ ⊢ \text{let } x = v_1 \text{ in } e_2 : σ_2$ by an application of rule POLY-LET. Then $DM^- ⊢ Γ ⊢ v_1 : σ_1$ and $DM^- ⊢ Γ, x:σ_1 ⊢ e_2 : σ_2$, where $x \notin \text{dom}(Γ)$, by smaller typing derivations. (Recall that the restriction on $DM^-$ ensures that the let-bound expression must be a value.) By induction it follows that $DM^- ⊢ |\{Γ\}|_{cbv} ▷ |\{v_1\}|_{cbv'} : |\{σ_1\}|_{cbv}$ and that $DM^- ⊢ |\{Γ\}|_{cbv} ▷ |\{x:σ_1\}|_{cbv} ⊢ |\{e_2\}|_{cbv'} : |\{σ_2\}|_{cbv}$. It is easy to check that $|\{v_1\}|_{cbv'}$ is always a value, and hence it follows that $DM^- ⊢ |\{Γ\}|_{cbv} ▷ |\{\text{let } x = v_1 \text{ in } e_2\}|_{cbv'} k : |\{σ_2\}|_{cbv}$, from which the result follows by the definition of the alternate term transform.
Suppose that $DM^- \vdash \Gamma \triangleright e : \forall t.\sigma$ by an application of rule \textsc{gen}. Then $DM^- \vdash \Gamma \triangleright e : \sigma$ by a smaller derivation, where $t \notin FTV(\Gamma)$. By induction $DM^- \vdash |\Gamma|_{cbv} \triangleright |e|_{cbv} : |\sigma|_{cbv}$, from which it follows that $DM^- \vdash |\Gamma|_{cbv} \triangleright |e|_{cbv} : \forall t.|\sigma|_{cbv}$ by an application of rule \textsc{gen}, from which the result follows by observing that $|\forall t.|\sigma|_{cbv} = \forall t.|\sigma|_{cbv}$.

Suppose that $DM^- \vdash \Gamma \triangleright e : [\tau/t]\sigma$ by an application of rule \textsc{inst}. Then $DM^- \vdash \Gamma \triangleright e : \forall t.\sigma$ by a smaller derivation, and thus, by induction, $DM^- \vdash |\Gamma|_{cbv} \triangleright |e|_{cbv} : \forall t.|\sigma|_{cbv}$. Consequently, $DM^- \vdash |\Gamma|_{cbv} \triangleright |e|_{cbv} : [||\tau||/t]|\sigma|$, which is sufficient for the result, by an application of Lemma 4.

Theorem 4 extends to $DM^- + \text{cont}$ by defining $||\tau\text{\textsc{cont}}||_{cbv} = ||\tau||_{cbv} \rightarrow \alpha$. We need only verify that $||\text{callcc}\text{\textsc{cont}}||_{cbv}$ and $||\text{throw}\text{\textsc{cont}}||_{cbv}$ given in Section 2, have the types $||\sigma_{\text{callcc}}\text{\textsc{cont}}||_{cbv}$ and $||\sigma_{\text{throw}}\text{\textsc{cont}}||_{cbv}$, respectively. The soundness of $DM^- + \text{cont}$ under call-by-value follows by the same reasoning as for $\lambda^- + \text{cont}$.

4.2. Call-by-Name

Theorem 3 (the Meyer-Wand-like typing theorem for call-by-name) can be extended to the unrestricted DM language.

Definition 10 (Call-by-Name Type Transform for DM)

\[
|\tau|_{cbn} = (||\tau||_{cbn} \rightarrow \alpha) \rightarrow \alpha \\
|\forall t.\sigma|_{cbn} = \forall t.|\sigma|_{cbn} \\
|t|_{cbn} = t \\
|b|_{cbn} = b \\
|\tau_1 \rightarrow \tau_2|_{cbn} = |\tau_1|_{cbn} \rightarrow |\tau_2|_{cbn} \\
|\forall t.\sigma|_{cbn} = \forall t.|\sigma|_{cbn}
\]

Lemma 5

1. $||[\tau/t]\sigma||_{cbn} = [||\tau||_{cbn} / t]|\sigma||_{cbn}$.
2. $|[\tau/t]\sigma|_{cbn} = [||\tau||_{cbn} / t]|\sigma|_{cbn}$.

Proof: By induction on the structure of $\sigma$.

Theorem 5
1. If $\text{DM} \vdash \Gamma \triangleright n : \sigma$, then $\text{DM} \vdash |\Gamma|_{\text{cbn}} \triangleright |n|_{\text{cbn}} : ||\sigma||_{\text{cbn}}$.

2. If $\text{DM} \vdash \Gamma \triangleright e : \sigma$, then $\text{DM} \vdash |\Gamma|_{\text{cbn}} \triangleright |e|_{\text{cbn}} : ||\sigma||_{\text{cbn}}$.

Proof: Similar to that of Theorem 4.

Theorem 5 extends to $\text{DM} + \text{cont}$ by defining $||\tau \text{cont}||_{\text{cbn}} = ||\tau||_{\text{cbn}} \rightarrow \alpha$. We need only verify that $||\text{callcc}||_{\text{cbn}}$ and $||\text{throw}||_{\text{cbn}}$, given in Section 2, have types $||\sigma_{\text{callcc}}||_{\text{cbn}}$ and $||\sigma_{\text{throw}}||_{\text{cbn}}$, respectively. The soundness of $\text{DM} + \text{cont}$ under call-by-name operational semantics follows from the extended theorem in a manner similar to that of the call-by-value case for $\text{DM}^-$.

4.3. Unrestricted Call-by-Value

Having established suitable typing properties for the variant call-by-value transform for $\text{DM}^-$ and the call-by-name transform for full $\text{DM}$, it is natural to consider whether there is a call-by-value CPS transform for full $\text{DM}$ that satisfies a Meyer-Wand-like typing property. The problem is to extend the CPS transform to general let expressions, i.e. those not necessarily satisfying the restriction that let-bound expressions be values.

Let us consider a naïve attempt to extend Theorem 4 to full $\text{DM}$ by considering the cbv term transform instead of the specialized cbv' transform. Consider the polymorphic let case. By induction we have $\text{DM} \vdash |\Gamma||_{\text{cbv}} \triangleright |e_1|_{\text{cbv}} : |\sigma_1||_{\text{cbv}}$ and $\text{DM} \vdash |\Gamma||_{\text{cbv}}, x : |\sigma_1||_{\text{cbv}} \triangleright |e_2|_{\text{cbv}} : |\tau_2||_{\text{cbv}}$, and we are to show that $\text{DM} \vdash |\Gamma||_{\text{cbv}} \triangleright \lambda k . |e_1|_{\text{cbv}} (\lambda x. |e_2|_{\text{cbv}} k) : |\tau_2||_{\text{cbv}}$. Since $e_1$ is a general computation, a continuation to receive its value (should it have a value) is required. But since $e_1$ may be polymorphic, the definition of $|\sigma||_{\text{cbv}}$ given earlier is no longer appropriate — we require that $|\sigma||_{\text{cbv}} = (||\sigma||_{\text{cbv}} \rightarrow \alpha) \rightarrow \alpha$, irrespective of whether or not $\sigma$ is a quantified type. The definition of $||\sigma||_{\text{cbv}}$ remains the same, in keeping with the intuition that a value of polymorphic type is a value of all instances of that type.

These modifications to the type transform take us beyond the Damas-Milner type system since now quantified types can occur as the domains of functions. Accordingly we generalize the target language of the CPS transform to the language $\text{DM}^+$ which is defined by eliminating the distinction between monotypes and polytypes in $\text{DM}$. The resulting system is equivalent to full polymorphic type assignment [16]. Although the decidability of type inference in $\text{DM}^+$ remains an open problem, this is not important for our purposes. The main property of $\text{DM}^+$ that we require is closure under $\beta$-reduction [16].
With these changes to the type transformation and the associated enrichment of the target type system, the putative proof of type preservation goes through in the case of \texttt{let} expressions, but now polymorphic generalization is problematic. Specifically, if $\textsf{DM} \vdash \Gamma \triangleright e : \sigma$ with $t \not\in \text{FTV}(\Gamma)$, then by induction $\textsf{DM}^+ \vdash \langle \Gamma \rangle_{cbv} \triangleright \langle e \rangle_{cbv} : \langle \sigma \rangle_{cbv}$, and $t \not\in \text{FTV}(\langle \Gamma \rangle_{cbv})$. It follows that $\textsf{DM}^+ \vdash \langle \Gamma \rangle_{cbv} \triangleright \langle e \rangle_{cbv} : \forall t.\langle \sigma \rangle_{cbv}$, but this is not enough — we must show that $\textsf{DM}^+ \vdash \langle \Gamma \rangle_{cbv} \triangleright \langle e \rangle_{cbv} : \forall t.\langle \sigma \rangle_{cbv}$, and there is no evident way to proceed.

In fact typing is not preserved. The argument proceeds by way of the extension of \textsf{DM} with continuation passing primitives. Under the call-by-value evaluation strategy, $\textsf{DM} + \texttt{cont}$ is unsound in that there is a term $e$ such that $e$ has a type $\tau$, but whose value when evaluated under call-by-value fails to have type $\tau$. Assuming that we have base types \texttt{int} and \texttt{bool}, and constants $0 : \texttt{int}$ and $\texttt{true} : \texttt{bool}$, the following term is well-typed with type \texttt{bool} in $\textsf{DM} + \texttt{cont}$ but evaluates under call-by-value to 0, a constant of type \texttt{int}:\footnote{This argument can be made without constants but at the cost of increased complexity. Constants of base type can easily be added to any of the transforms presented in this paper by defining $\langle c \rangle = c$, where $c$ is a constant. Constants of non-base type must be handled on a case-by-case basis.}

$$e_0 \ = \ \begin{array}{l}
\text{let } f \ \texttt{be callcc} (\lambda k.\lambda x.\texttt{throw } k \lambda y.x) \\
\text{in } (\lambda x.\lambda y.y) (f 0) (f \texttt{true})
\end{array}$$

Using the typing rules of $\textsf{DM} + \texttt{cont}$, the \texttt{let}-bound identifier $f$ is assigned the type $\forall t.t \to t$, and hence may be used at types $\texttt{int} \to \texttt{int}$ and $\texttt{bool} \to \texttt{bool}$ in the body. But the binding for $f$ grabs the continuation associated with the body of the \texttt{let} expression and saves it. Upon evaluation of $f 0$, the continuation is invoked and $f$ is effectively re-bound to a constant function returning 0. The body is re-entered, $f 0$ is evaluated once again (without difficulty), but then $f \texttt{true}$ is evaluated, resulting in 0.

It follows that the call-by-value CPS transform for $\textsf{DM} + \texttt{cont}$ does not preserve typability in the sense of Meyer & Wand, for by the correctness of the call-by-value CPS transform for $\textsf{DM} + \texttt{cont}$, the expression $\langle e_0 \rangle \lambda x.x$ also evaluates to 0 (under call-by-name or call-by-value), yet has type \texttt{bool}, a violation of the subject reduction property of $\textsf{DM}^+$ \cite{16}. Consequently the call-by-value CPS transform does not verify the Meyer-Wand typing property even in the absence of continuation-passing primitives. For otherwise we could extend such a transform for the pure \textsf{DM} language to $\textsf{DM} + \texttt{cont}$ by first regarding \texttt{callcc} and \texttt{throw} as variables, and then replacing them by the expressions $\langle \texttt{callcc} \rangle_{cbv}$ and $\langle \texttt{throw} \rangle_{cbv}$. The substitution preserves typing, and results in a correct call-by-value CPS transform for $\textsf{DM} + \texttt{cont}$, which is impossible.
It is natural to inquire whether there is some other CPS transform for the pure DM language (without continuation-passing primitives) that is correct for the call-by-value interpretation and satisfies the Meyer-Wand typing property. Although we are unaware of such a transform, it is difficult to prove that none exists, in part because it is unclear what, in general, constitutes a correct CPS transform of an expression. We are assured, however, that any such transform must be substantially different from the standard call-by-value transform and its close relatives.

**Theorem 6** There is no call-by-value CPS transform $|e|$ for DM satisfying the following two conditions:

1. **Equivalence:** $|e|$ is operationally equivalent to $|e|_{cbv}$ under either the call-by-value or call-by-name operational semantics.\(^5\)

2. **Typing:** If $\text{DM} \vdash \Gamma \triangleright e : \sigma$, then $\text{DM}^+ \vdash \left[\left[|\cdot\right|\right]_{cbv} \triangleright e \triangleright : \left[|\sigma|\right]_{cbv}$.

**Proof:** Let $e'_0 = [c/callcc, t/throw]e_0$, where $e_0$ is as in the counterexample above, so that $e_0 = [\text{callcc}/c, \text{throw}/t]e'_0$. Under the assumptions of the theorem, $|e'_0|$ is operationally equivalent to $|e'_0|_{cbv}$, and

$$\text{DM}^+ \vdash c : \left[\left[|\sigma|\right]_{\text{callcc}, cbv}, t : \left[\left[|\sigma|\right]_{\text{throw}, cbv}\right]\triangleright e'_0 : \left[\left[\text{bool}\right]\right]_{cbv}.$$

Now since

$$\text{DM}^+ \vdash \cdot \triangleright \left[\left[|\text{callcc}|\right]_{cbv} : \left[\left[|\sigma|\right]_{\text{callcc}}\right]_{cbv}\right]$$

and

$$\text{DM}^+ \vdash \cdot \triangleright \left[\left[|\text{throw}|\right]_{cbv} : \left[\left[|\sigma|\right]_{\text{throw}}\right]_{cbv}\right],$$

it follows that

$$\text{DM}^+ \vdash \left[\left[|\text{callcc}|\right]_{cbv}/c, \left[\left[|\text{throw}|\right]_{cbv}/t]\right]\triangleright e'_0 : \left[\left[\text{bool}\right]\right]_{cbv}.$$

Now

$$\left[\left[|\text{callcc}|\right]_{cbv}/c, \left[\left[|\text{throw}|\right]_{cbv}/t]\right] | e'_0 |_{cbv}$$

is operationally equivalent to

$$\left[\left[|\text{callcc}|\right]_{cbv}/c, \left[\left[|\text{throw}|\right]_{cbv}/t]\right] | e'_0 |.$$

But the former term is just $|e_0|_{cbv}$ as defined in Section 2. By the correctness of this transform with respect to the call-by-value operational semantics, we have that $|e_0|_{cbv} (\lambda x . x)$ evaluates to 0, and hence

$$\left[\left[|\text{callcc}|\right]_{cbv}/c, \left[\left[|\text{throw}|\right]_{cbv}/t]\right] | e'_0 | (\lambda x . x)$$

must also evaluate to 0. But the latter term has type bool, in contradiction to the subject reduction property of $\text{DM}^+$. \(\blacksquare\)

---

\(^5\)Two terms $e_1$ and $e_2$ are operationally equivalent iff they are indistinguishable in all program contexts [18].
The conditions of the theorem leave open the possibility of there being a call-by-value transform for DM that is operationally inequivalent to the standard one, or of there being a type transform for which a Meyer-Wand-like type preservation theorem can be proved but for which either \texttt{|callcc|}_{\text{cbv}} or \texttt{|throw|}_{\text{cbv}} fails to have the required type. The typing condition seems natural and well-motivated; we know of no other uniform assignment of types for which the call-by-value CPS transform validates a Meyer-Wand-like type preservation theorem. On the other hand, the requirement of operational equivalence is rather strong. In particular, it imposes stringent conditions on the transformation of terms with free variables which we exploited in the proof of the theorem. It seems plausible that a variant transform that fails to satisfy the operational equivalence criterion may exist, but we have no evidence to support this conjecture.

4.4. Related Transforms

It seems worthwhile, however, to point out that there is a variant type transform that “almost” works. This transform is defined by taking $\|\forall t.\sigma\| = \forall t.\|\sigma\|$, and $\|\sigma\| = (\|\sigma\| \to \alpha) \to \alpha$. The intuition behind this choice is to regard polymorphic instantiation as a “serious” computation (in roughly the sense of Reynolds [19]). This interpretation is at variance with the usual semantics of ML polymorphism since it admits primitives that have non-trivial computational effects when polymorphically instantiated. Nevertheless, we can use this type transform to extend the Meyer-Wand theorem to a variant call-by-value CPS transform for $\text{DM}^-$ and to a variant call-by-name CPS transform for $\text{DM}$, provided that we restrict attention to programs of monomorphic type. It does not provide a variant call-by-value CPS transform for full $\text{DM}$ because of the way in which polymorphic generalization is handled.

To make these observations precise, we sketch the definitions of variant CPS transforms based on this type interpretation. The main idea is to define the CPS transform by induction on typing derivations so that the effect of polymorphic generalization and instantiation can be properly handled. We give here only the two most important clauses, those governing the rules GEN and INST:

\[
\begin{align*}
|\Gamma \vdash e : \forall t.\sigma| &= \lambda k. |e|, \text{ where } \\
|\Gamma \vdash e : \sigma| &= |e|
\end{align*}
\]

\[
\begin{align*}
|\Gamma \vdash e : [\tau/t]\sigma| &= \lambda k. |e| \ (\lambda x.x \ k), \text{ where } \\
|\Gamma \vdash e : \forall t.\sigma| &= |e|
\end{align*}
\]

This definition may be extended to the other inference rules in such a way as to implement either a call-by-name or call-by-value interpretation of
application. However, the transform fails (in general) to agree with the usual (call-by-value or call-by-name) ML semantics on terms of polymorphic type. Specifically, the transformation of a GEN rule applies the current continuation to the suspended computation of $e$. If this continuation is not strict, then an expression that would abort in ML terminates normally after transformation into CPS. For example, suppose that $\text{hd}$ and $\text{nil}$ are constants with polymorphic types $\forall t. t\text{list} \rightarrow t$ and $\forall t. t\text{list}$, respectively. We may derive the judgement $\bullet \triangleright \text{hd\,nil} : \forall t. t\text{list}$ using the given typings for $\text{hd}$ and $\text{nil}$, and the rules for application and polymorphic generalization. Using the variant rules given above, the transform of $\text{hd\,nil}$ determined by this typing derivation has the form $\lambda k. k \mid \text{hd\,nil}$. But this expression evaluates normally on a non-strict continuation $k$, whereas under the usual ML semantics the expression should abort regardless of whether it is used in a subsequent computation.

By restricting attention to programs of monomorphic type, we may obtain correct variant CPS transforms for $\text{DM}^-$ (under call-by-value) and $\text{DM}$ (under call-by-name). This is essentially because in $\text{DM}^-$ under call-by-value there are no non-trivial polymorphic computations, and because in $\text{DM}$ under call-by-name the semantics is defined by substitution. But the above argument shows that the variant call-by-value transform is incorrect for $\text{DM}$ under call-by-value. Specifically, it fails to correctly implement the usual ML semantics for expressions such as $\text{let } x = \text{hd\,nil} \text{ in } 0$ (which, under the above transformation, yields result 0). This suggests that it would be advantageous to separate the two roles of $\text{let}$ in ML. Specifically, our results imply the soundness of the variant of ML obtained by evaluating $\text{let}$'s sequentially but admitting no polymorphism, and by adding a new definition form, $\text{def } x = e_1 \text{ in } e_2$, which admits polymorphism but is evaluated “by name”.

5. Conclusion

The Meyer-Wand typing theorem for the call-by-value CPS transform for the simply-typed $\lambda$-calculus establishes a simple and natural relationship between the type of a term and the type of its call-by-value CPS transform. Meyer and Wand exploited this relationship in their proof of the equivalence of the direct and continuation semantics of $\lambda^-$ [13]. A minor extension of this result may be used to establish the soundness of typing for $\lambda^- + \text{cont}$, the extension of $\lambda^-$ with continuation-passing primitives [4], under call-by-value.

In this paper we have presented a systematic study of the extension of the Meyer-Wand theorem to the Damas-Milner system of polymorphic type assignment. Our main positive results are the extension of the Meyer-Wand
theorem to the call-by-value interpretation of a restricted form of polymorphism, and to the call-by-name interpretation of the unrestricted language. These results have as a consequence the soundness (in the sense of Damas and Milner [2]) of these programming languages. We have also argued that there is no “natural” call-by-value CPS transform for the unrestricted language, but this leaves open the possibility of finding a transformation that is radically different in character from the usual one.

Our investigation makes clear that there is a fundamental tension between implicit polymorphism and the call-by-value interpretation of let. This is consistent with earlier results establishing the inconsistency between unrestricted polymorphism and polymorphic reference types [22, 12] and first-class continuations [9, 10]. The source of the inconsistency may be traced to conflicting motivations for the static and dynamic semantics of the language. The polymorphic typing rule for let is motivated by a substitution principle — a let-bound variable is deemed to have exactly those types that may be ascribed to the expression to which it is bound. In particular, if a let-bound variable may be used at multiple types, provided that each of these may be ascribed to the bound expression separately.

But this principle, appealing though it may be in isolation, is inconsistent with the “evaluate-once” semantics of let expressions in the call-by-value dynamic semantics. In a pure functional language it is possible to combine both principles without complication, achieving polymorphism without sacrificing code re-use. Once control or store effects are admitted, however, it becomes untenable to maintain both principles without restriction. We have outlined a CPS transform for the full Damas-Milner language that extends to continuation-passing primitives, but which is not quite equivalent to the usual call-by-value semantics. This suggests that a language in which polymorphic generalization and instantiation are semantically significant would be a well-behaved alternative to ML-style implicit polymorphism. This perspective has been explored in some detail in subsequent work of the authors [11].
